## OBJECTIVES

- ◆ We will discuss foundations and applications related to decompression
  - underlying physiological/mathematical relationships
  - decompression procedures
    - ◆ air diving tables
      - US Navy
      - DCIEM\*
        - \*Defence and Civil Institute of Environmental Medicine
      - alternative tables
    - ◆ treatment tables
  - decompression algorithms and dive computers
  - flying after diving
  - altitude diving

NW Pollock, PhD

NW Pollock, PhD

## LINEAR GAS PRESSURE-VOLUME RELATIONS IN SEAWATER

Depth (fsw / msw)	Pressure (ATA)	Pressure			Volume	Density
		(lb-in <sup>-2</sup> )	(bar)	(kPa)		
0 / 0	1	14.7	1.01	101.3	1	1x
33 / 10	2	29.4	2.03	202.6	1/2	2x
66 / 20	3	44.1	3.04	303.9	1/3	3x
99 / 30	4	58.8	4.05	405.2	1/4	4x
132 / 40	5	73.5	5.07	506.5	1/5	5x
165 / 50	6	88.2	6.08	607.8	1/6	6x

- ◆ Critical relationships to understand the physiological impact of diving
  - sea level pressure references are convenient, but not always the most relevant

NW Pollock, PhD

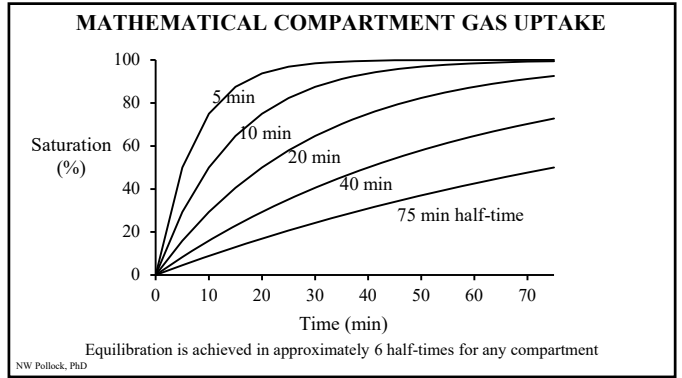

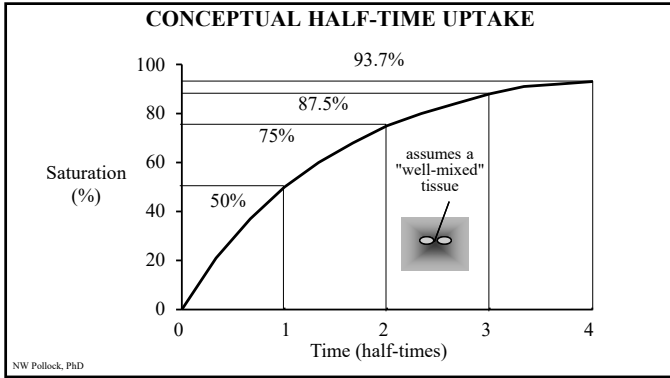

NW Pollock, PhD

## CRITICAL CONCEPTS IN INERT GAS EXCHANGE

- ◆ **Gas Uptake/Elimination**
  - uptake (ongassing) and elimination (offgassing) follow pressure gradients
  - half-times can predict for a range of mathematical constructs ("compartments")
    - ◆ eg, 5, 10, 20, 40, 60, 120 min, etc.
    - equilibration is presumed to be complete in ~6 half-times in static conditions
      - Pollock and Buteau (2017)
- ◆ **Supersaturation**
  - gas pressure<sub>issue</sub> > gas pressure<sub>ambient</sub>
  - Haldane conducted saturation experiments with animals
    - ◆ reported a maximum safe 2:1 pressure reduction ratio
    - since N<sub>2</sub> is 78% of air mixture, 1.56:0.78 for N<sub>2</sub>
    - ◆ now known to be more complicated
- ◆ **M-value**
  - maximum tissue tension in supersaturation that can be tolerated without problem
    - ◆ theoretical construct - both bubbles and DCS can develop within M value limits
    - ◆ note: faster tissues have higher M-values

NW Pollock, PhD

### MODELING PHYSIOLOGY

- ♦ Models provide manageable representations of complex events
  - sophistication increases as a function of understanding and technical capabilities (eg, measurement and computational power)
- ♦ Models will almost inevitably be incomplete and probably at least partially wrong
  - but they can still be useful

Examples of conceptual physiological models

NW Pollock, PhD

### DECOMPRESSION STRESS CONTINUUM

← ? True Safety Threshold ? →

- ♦ Reality - DCS is a probabilistic event
- ♦ Risk tolerance is personal, but should be informed

NW Pollock, PhD

## US NAVY DIVE TABLES

- ◆ Developed by US Navy for military use but escaped into the civilian world
  - developed mathematically with limited human testing
  - liberation fueled rapid growth of recreational diving in 1950s
  - latest version in Revision 7 of US Navy dive manual
    - USN (2016) - available for free download
- ◆ Structure
  - single or repetitive exposures
  - not intended for multi-level computation

NW Pollock, PhD

**Table 9-8. Residual Nitrogen Time Table for Repetitive Air Dives.**

Locate the diver's repetitive group designation from his previous dive along the diagonal line above the table. Read horizontally to the column in which the diver's surface interval falls. Read vertically down to the row in which the diver's depth interval falls. The number in the cell is the residual nitrogen time (RNT) in minutes. If the RNT is 0, the diver is considered to be at the surface for the purpose of the next dive. If the RNT is 15 minutes or more, the diver is considered to be at the surface for the purpose of the next dive. If the RNT is 15 minutes or more, the diver is considered to be at the surface for the purpose of the next dive.

**Table 9-8. Residual Nitrogen Time Table for Repetitive Air Dives.**

Locate the diver's repetitive group designation from his previous dive along the diagonal line above the table. Read horizontally to the column in which the diver's surface interval falls. Read vertically down to the row in which the diver's depth interval falls. The number in the cell is the residual nitrogen time (RNT) in minutes. If the RNT is 0, the diver is considered to be at the surface for the purpose of the next dive. If the RNT is 15 minutes or more, the diver is considered to be at the surface for the purpose of the next dive. If the RNT is 15 minutes or more, the diver is considered to be at the surface for the purpose of the next dive.

**"Repetitive Dive SI"**  
10 min - 15:50 h:min  
USN (2016)

### US NAVY DIVE TABLES 9-7/9-8 - AIR NO DECOMPRESSION (2016)

Max depth  
66 ft (20 m)

RG H  
SI 2:20  
F  
45 ft (14 m)  
40 min ABT  
48 min RNT  
88 min ESDT

SI 1:30  
J  
40 ft (12 m)  
38 min ABT  
97 min RNT  
135 min ESDT

SI 1:30  
M  
40 ft (12 m)

US Navy tables compute decompression status based on maximum dive depth and actual bottom time (ABT) to compute a repetitive group (RG). The RG falls as the post-dive surface interval (SI) increases. The impact of previous dives on the next dive is computed with residual nitrogen time (RNT). (ABT + RNT = ESDT [equivalent single dive time]). ESDT is entered to compute the RG for repetitive dives.

NW Pollock, PhD

### US NAVY DIVE TABLE 9-9 - AIR DECOMPRESSION (2016)

Max depth  
82 ft (25 m)

RG J  
SI 1:20  
I  
52 ft (16 m)  
35 min ABT  
58 min RNT  
93 min ESDT

SI 1:20  
O  
20 ft (6 m)  
17 min

SI 2:00 M  
SI 7:00 G  
SI 12:00 B

Dive tables require interim stops during ascent when the exposure exceeds no-decompression limits. These allow additional time for off-gassing before the remaining step(s) in the decompression occurs. The repetitive group (RG) at the end of a dive decreases alphabetically as the post-dive surface interval (SI) lengthens and excess inert gas is eliminated until the diver is "off the tables" (or does another dive to accumulate more inert gas).

NW Pollock, PhD

**Table 9-9. Air Decompression Table (Continued).**  
(DESCENT RATE 75 FPM—ASCENT RATE 30 FPM)

Bottom Time (min)	Time to First Stop (M:S)	Gas Mix	DECOMPRESSION STOPS (FSW)								Total Ascent Time (M:S)	Chamber O <sub>2</sub> Periods	Repet Group

		AIR/O <sub>2</sub>									26	27:50		

**USN (2016)**

### RECREATIONAL VARIANTS

- Many recreational variants based on the US Navy dive tables exist
  - more conservative no-decompression limits
    - eg. NAUI, SSI
  - more liberal no-decompression limits
    - eg. PADI recreational dive planner
- note: typically include some steps beyond no-decompression limits

NW Pollock, PhD

### DCIEM DIVE TABLES

- Developed by Canadian military
  - based on 1962 Kidd-Stubbs four compartment serial model
    - the goal was to develop tables more conservative than those of the US Navy
  - largest manned dive verification testing effort
    - 1800 person-dives in initial series
      - endpoints of DCS and aurally monitored vascular bubbles
  - conservative limits set based on Doppler ultrasound
    - very limited bubble grades III-IV bubbles allowed (0-IV scale)
  - current air diving tables approved in 1992
    - DCIEM (1992)
- Structure
  - single or repetitive exposures
  - allow multi-level profile computation
  - provide some altitude correction
- Algorithm developed for dive computer implementation by Shearwater in 2020

NW Pollock, PhD

### NO-DECOMPRESSION LIMITS (in min)

Depth (m/ft)	USN (2016)	DCIEM	% Δ
9 / 30	371	300	-19
12 / 40	163	150	-8
15 / 50	92	75	-18
18 / 60	63	50	-21
21 / 70	48	35	-27
24 / 80	39	25	-36
27 / 90	33	20	-39
30 / 100	25	15	-40
33 / 110	20	12	-40
36 / 120	15	10	-33
39 / 130	12	8	-33
42 / 140	10	7	-30
45 / 150	8	6	-25

- DCIEM no-decompression limits were adjusted based on symptoms and high grade bubbles observed in testing, contributing to the inconsistent differences from the USN table limits

NW Pollock, PhD

### DIVE TABLE COMPARISON

- No decompression limits for first dive
- There is a pretty good chance that there is no simple truth with this degree of variability
- No decompression limits for second dive
  - first dive: 60 fsw (18 msw) for 50 min followed by a 60 min surface interval

Depth (ft/m)	USN 2016	DCIEM	RDP	HUGI	Doppler	Max Δ (%)
40 / 12	163	150	140	135	130	+25
50 / 15	92	75	80	75	70	+31
60 / 18	63	50	55	50	50	+26
70 / 21	48	36	40	40	40	+33
80 / 24	39	25	30	30	30	+56
90 / 27	33	20	25	25	25	+65
100 / 30	25	15	20	20	20	+67

  

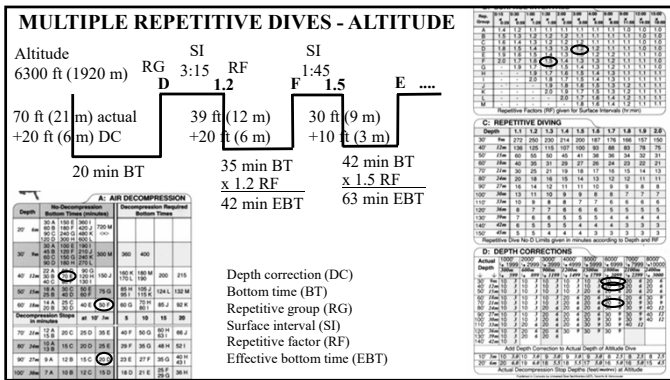

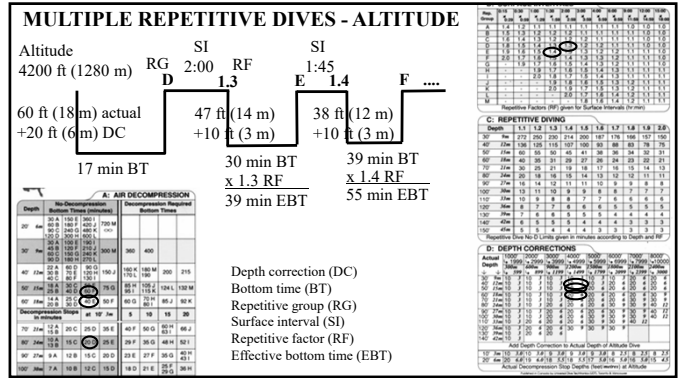

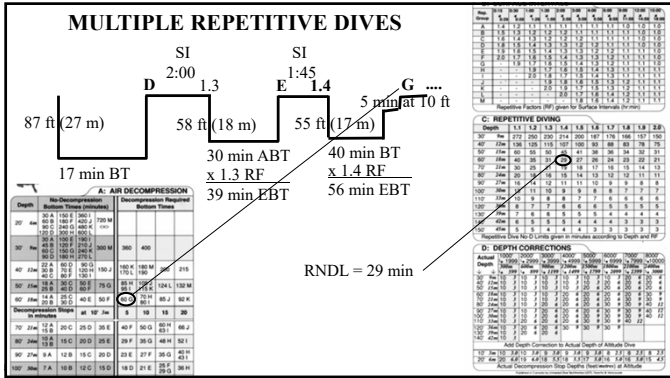

Depth (ft/m)	USN 2016	DCIEM	RDP	HUGI	Doppler	Max Δ (%)
40 / 12	89	93	103	43	57	+140
50 / 15	35	38	52	18	14	+271
60 / 18	17	26	32	7	6	+433
70 / 21	9	17	21	7	3	+600
80 / 24	6	13	13	4	-	-
90 / 27	4	10	10	4	-	-
100 / 30	-	8	7	4	-	-

NW Pollock, PhD

### USE OF DCIEM DIVE TABLES

- Required for some diving in several countries
  - eg, Canada, Australia, New Zealand
  - commercial and scientific
- Good option for persons sensitive to or concerned with decompression stress
  - now available in Shearwater dive computers
  - implementation complete; manned trials began in 2019 at DRDC in Toronto

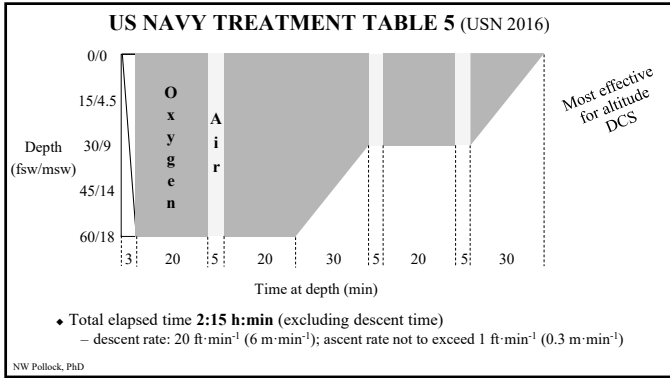

NW Pollock, PhD

### ADDITIONAL DIVE TABLES

- Enriched air nitrox (EAN)
  - increased oxygen / decreased nitrogen
  - mathematically corrected for nitrogen fraction
    - thus iso-risk diving nitrox to limit of nitrox tables or air to limit of air tables
  - risk of oxygen toxicity is increased
    - PO<sub>2</sub> is generally limited to 1.4 atm during working phase of dives
- Surface decompression (surD)
  - divers brought to surface after 40 fsw (12 msw) stop to finish deco in chamber
- Mixed gas
  - eg, trimix - oxygen, helium, nitrogen
- Treatment tables
  - US Navy 6, 5, 6A, 9
  - Catalina
  - COMEX

NW Pollock, PhD

### DIVE COMPUTERS

- Have allowed a seismic shift in dive planning
  - enabling complex dive profiles with minimal effort
- Many decompression algorithms (mathematical models) and versions used
  - substantial variability in both limits and testing
- Provide only first order approximation of risk
  - they should be used thoughtfully, with caution

NW Pollock, PhD

## POPULAR DECOMPRESSION ALGORITHMS

- ◆ **Multi-Tissue Model** (Haldane)
  - original gas content model; uptake/elimination half-time basis
- ◆ **Buhlmann**
  - empirically-derived; code openly released
- ◆ **DCIEM** (Defence and Civil Institute of Environmental Medicine)
  - empirically-derived; 1800 Doppler-monitored person-dives
- ◆ **VPM** (Varying Permeability Model) (Yount)
  - mathematically-derived bubble model; code openly released
- ◆ **RGBM** (Reduced Gradient Bubble Model) (Wienke)
  - mathematically-derived bubble model; follows VPM; proprietary
- ◆ **VVAL-79**
  - used in US Navy revision 7 (2016) air diving tables
- ◆ **DSAT** (Diving Safety and Technology / Recreational Dive Planner)
  - repetitive dive limits based on 60 min instead of 120 min half-time

NW Pollock, PhD

Inert gas uptake and decompression risk are much greater with square profiles than with multi-level profiles.

NW Pollock, PhD

## DECOMPRESSION - FOUNDATIONS

- ◆ Decompression stress is a function of relative pressure change
  - ascent during diving
  - ascent from surface to altitude
    - eg. flying or driving

NW Pollock, PhD

## DECOMPRESSION STRESS - SURFACE OR FLY

NW Pollock, PhD

## DECOMPRESSION SAFETY FOR FLYING

- ◆ DCS risk low for most flying
  - most unpressurized aircraft fly at altitudes less than 12,000 ft (3658 m; ~0.65 atm abs)
- ◆ FAR\* require pressurized craft to be able to maintain a cabin altitude of  $\leq 8000$  ft (2438 m; ~0.76 atm abs) at maximum cruise altitude
  - \*Federal Aviation Regulations

Dive hole at Gneiss Pt, Antarctica

NW Pollock, PhD

## CABIN PRESSURE DIFFERENTIAL

Altitude (ft [m])	$P_{out}$ (atm abs)	$\Delta P$ (psi)	$P_{in}$ (atm abs)	Cabin Altitude (ft [m])
sea level	1.00			
24,000 [7315]	0.39	4.0	0.66	11,000 [3353]
		8.0	0.93	2000 [610]
		10.0	1.07	---
36,000 [10,973]	0.22	4.0	0.50	18,000 [5,486]
		8.0	0.77	7000 [2134]
		10.0	0.90	2750 [838]
48,000 [14,630]	0.12	4.0	0.40	23,500 [7163]
		8.0	0.67	11,200 [3414]
		10.0	0.80	6000 [1829]

Stepanek et al. (2021)

NW Pollock, PhD

### ALTITUDE DECOMPRESSION SICKNESS

- ◆ **Threshold altitude for DCS?**
  - 16,000-19,000 ft (4900-6400 m; 0.54-0.48 atm abs)
    - Houston (1947); Davis et al. (1971); Haske and Pilmanis (2002)
  - <14,000 ft (4267 m)
    - Files et al. (2005)
  - 11,000 ft (3350 m; 0.66 atm abs) - direct ascent from near sea level and physical exercise (combined events atypical)
    - Kumar et al. (1990)
- ◆ **Threshold duration at altitude for DCS?**
  - insufficient data
  - activity level, pressure profile and decompression rate will all influence threshold altitude
- ◆ **Flying after diving can increase decompression stress**

NW Pollock, PhD

### CURRENT FLYING AFTER DIVING GUIDANCE

- ◆ **US Federal Aviation Regulations** - have Guidelines Only
  - 12 h surface interval (SI) after no-decompression dives (max 8000 ft cabin altitude)
  - 24 h SI after decompression dives (max 8000 ft cabin altitude)
  - 24 h SI after any dive if cabin altitudes >8000 ft (2438 m; 75.3 kPa)
    - Aeronautical Information Manual (2023)
- ◆ **Divers Alert Network (DAN) Consensus Guidelines**
  - 12 h SI after single no-decompression dives (2000-8000 ft [610-2438 m] cabin altitude)
  - 18 h SI after multiple dives per day or multiple diving days
  - 'substantially longer than 18 h SI' after decompression dives
    - Sheffield and Vann (2004)
- ◆ **Health Canada Regulations**
  - 12 h following a no-decompression dive
  - 24 h following a decompression dive
  - such time as specified by a physician who treated the diver for a pressure-related injury
    - Canada OHS Regulations (SOR/86-304) (2023)
- ◆ **Common guidance calls for 24-h pre-flight surface interval**

NW Pollock, PhD

### ALTITUDE EXPOSURE AFTER DIVING TABLES

- ◆ **US Navy**
  - based on available data with much interpolation/extrapolation
  - 2016 - Table 9-6
    - USN Dive Manual (2016)
  - less conservative but more flexible option
    - similar to computations used in some dive computers

NW Pollock, PhD

### EXCERPT: USN TABLE 9-6 - REQUIRED SURFACE INTERVAL BEFORE ASCENT TO ALTITUDE AFTER DIVING (2008; 2016)

		Increase in Altitude (ft)				
		2000	4000	6000	8000	10,000
Repetitive Group Designator	F	0:00	0:00	1:32	7:06	15:20
	G	0:00	0:00	3:38	9:13	17:27
	H	0:00	1:06	5:29	11:04	19:18
	I	0:00	2:45	7:09	12:44	20:58
	J	0:41	4:15	8:39	14:13	22:27
	K	2:03	5:37	10:00	15:35	23:49
	L	3:18	6:52	11:15	16:50	25:04
	M	4:28	8:01	12:25	18:00	26:14
	N	5:32	9:06	13:29	19:04	27:18
	O	6:33	10:06	14:30	20:05	28:19
Z	7:29	11:03	15:26	21:01	29:15	

still based on much interpolation / extrapolation

NW Pollock, PhD

### USN TABLE 9-5 - REPETITIVE GROUPS ASSOCIATED WITH INITIAL ASCENT TO ALTITUDE (2008; 2016)

Altitude (ft)	Repetitive Group	Altitude (m)
1000	A	305
2000	A	610
3000	B	914
4000	C	1219
5000	D	1524
6000	E	1829
7000	F	2134
8000	G	2438
9000	H	2743
10,000	I	3048

NW Pollock, PhD

### ALTITUDE DEPTH CORRECTION

- ◆ Effectively, any depth at altitude has the impact of a deeper depth at sea level
- ◆ Altitude correction allows adjusted depth to be used with normal dive tables

$$\text{'Equivalent Depth'} = \text{Altitude Depth} * \frac{\text{Sea Level Pressure}}{\text{Altitude Pressure}}$$

-US Navy Dive Manual (2016)

$$\text{- eg, equivalent depth} = 18 \text{ m (60 ft)} * \frac{1013 \text{ mb}}{843 \text{ mb}} = 22 \text{ m (72 ft)}$$

Lake Minnewanka, Alberta  
(1372 m; 4500 ft altitude)

NW Pollock, PhD

## DECOMPRESSION AND ALTITUDE DIVING

- ◆ 'Equivalent depth' may be most reasonable to use for conservative no-decompression diving only
- ◆ Tolerable tissue gas tension to ambient pressure ratios may vary as a function of altitude
  - DCS models differ substantially between ocean diving exposures and altitude exposures
  - potential confounders with much of the available data include immersion, exercise and thermal stress
- ◆ A limited number of decompression models incorporate altitude computations
  - eg, DCIEM, Buhlmann
    - Boni et al. (1976); Egi and Brubakk (1995); Egi and Gurmen (2000)

NW Pollock, PhD

## TAKE HOME MESSAGES

- ◆ Decompression status is predicted by mathematical models
  - imperfectly, but reliably; based on tissue compartments models
- ◆ Dive tables represent a single compartment model
  - ◊ key: US Navy, DCIEM, and treatment (USN TT6 and TT5, Catalina, Comex 30)
  - largely supplanted by multi-compartment dive computer algorithms
- ◆ Key concepts in decompression modeling/execution
  - gas uptake and elimination (and half-times)
  - supersaturation and undersaturation states
  - M-value as mathematical estimator of safe supersaturation limit for given tissue
  - relative pressure change is inversely proportional to depth
- ◆ Diver behavior can play a critical role in moderating exposure stress
- ◆ Altitude exposure increases decompression stress
  - diving at altitude
  - travel to altitude (flying or driving) after diving

NW Pollock, PhD
